

OrionERP App Summary

Evidence basis: OrionERP.sln, OrionERP.Web Program/DI, feature pages, and CI/global.json

What it is

OrionERP is a modular monolith ERP built on ASP.NET Core and Blazor Server with SQL Server. Current implemented modules focus on CFDI/SAT workflows, accounting operations, and financial reporting.

Who it is for

Primary persona: accounting and SAT operations users at Bonhomia Suites, plus administrators.

What it does

- Registers and switches RFC context for multi-RFC operations.
- Handles SAT massive-download lifecycle: request, verify, download, and package processing.
- Loads and processes SAT XML files through an inbox pipeline.
- Manages accounting transactions (polizas), including CFDI linking and attachments.
- Provides banking/accounting workflows under Contabilidad.
- Shows financial reports: Hoja de Trabajo, Balanza de Comprobacion, and Estado de Perdidas y Ganancias.

How it works (repo-evidenced architecture)

- UI layer: Blazor Server pages/components in OrionERP.Web with role-based authorization.
- Application layer: OrionERP.Application contracts and DTOs.
- Infrastructure layer: OrionERP.Infrastructure services implemented with Dapper, EF Core, and stored procedures.
- External integration: Sat.MassiveDownload SOAP client for SAT auth/request/verify/download endpoints.
- Data flow: page action -> interface/service via DI -> SQL Server and/or SAT API -> rendered result.
- Security: ASP.NET Identity cookie auth, RFC-aware authorization handler, and DataProtection keys in App_Data.

How to run (minimal)

- Install .NET SDK 10.0.100 (global.json).
- Set ConnectionStrings:OrionDb in src/OrionERP.Web/appsettings.json.
- Run: dotnet restore OrionERP.sln
- Build: dotnet build OrionERP.sln -c Debug
- Start web app: dotnet run --project src/OrionERP.Web
- Open Development URL from launchSettings.json: https://localhost:7089 or http://localhost:5221

Not found in repo: documented local DB provisioning/migration steps and default seed credentials.
